A: Your best bet would be to use an Android OIDC provider. There are a variety of options, see and Some of them are: They all implement OIDC, and while the first two are Firebase based, the third is a completely open source implementation. I would advise looking at the code samples on and trying the ones you find most interesting and add the OIDC provider you like best. Q: sorting n-tier architecture I have read a little about the "tiers" of an n-tier architecture, and i understand how the 3-tier architecture works, but how does a four-tier architecture work? How does it differ from the 3-tier architecture? There are 2 concepts to think about when designing a 4-tier architecture. 1 - If you look at the number of tiers, you can do it for your four tier

architecture in a 3-tier style. You just need to identify which layer is the front end and which are the two back end (or more) tiers. 2 - You have to start thinking about how you will access data, in the 2-tier architecture. You need to make sure that your API and the data will be totally separated. According to the definition of n-tier architecture : An n-tier architecture is a software design pattern that consists of one or more layers that are typically represented by a grid with a number of horizontal and vertical squares or rectangles. In a four-tier architecture it consists of a presentation tier, business tier, data access tier and a data access tier as follows : Presentation Tier : There is a web server that hosts the web pages of your website which is called a presentation tier. Business Tier : This is the layer where your business logic lies. It executes all business related activities. Data

access tier : In a 4-tier architecture, there
