As of May 2017, nearly 10 million AutoCAD users were using AutoCAD, according to the 2016 Q3 AutoCAD Users Survey by TechTarget's research division. AutoCAD adopts the concept of a raster image, which is similar to a picture made from scanning an image onto film (or, for less expensive scanners, scanned directly onto paper). These images can be printed, viewed in slide shows, and so on. Unlike vector graphics, which are defined in terms of mathematical equations (see below), a raster image is formed by scanning objects. A traditional layout is a raster drawing; a viewport is a raster image. Most newer version of AutoCAD (2013 and newer) support Smart Guides and workflows that give layout support to 2D drawings with a viewport. The primary raster image is called the paper space and is used to store drawing contents; the paper space is a viewport of a sheet of paper. The paper space is the area of the drawing that represents the viewport. While most versions of AutoCAD use a Windows operating system, Autodesk also supports AutoCAD for macOS and AutoCAD LT for Linux. The main use of AutoCAD is to design and create mechanical and architectural projects such as buildings, bridges, roads, railroads, ships, bridges, car interiors, furniture and automobiles. Other applications include graphic and electronic design; printed circuit design; maintenance and repair of existing systems; utilities, piping, and drainage systems; and engineering management. History Raster (electronic) The raster electronic image was born when the first "computer-aided drafting" machines were introduced into the early 1960s. The CAD operator was required to make a human-readable drawing from a tape of punched holes (stored on tape or punched onto paper as punch tape). When the human-readable drawings were viewed in a visual display (often on a cathode ray tube), an operator could use tools, such as a mouse, to place a line, circle, arc, or polyline on the display, a process that is similar to a mouse click. By the mid-1960s, CAD operators were often required to use these punched-tape-based systems as well as a CRT, and it was assumed that the operator could read and store the resulting punched tape in a machine's memory. In 1966, the

Excessive or inadequate use of SCD in these patients may lead to anemia or renal failure, respectively. Finally, in healthy young people in whom the use of SCD is not necessary, even a short period of use may be associated with development of hemochromatosis (HCH), a chronic metabolic iron storage disorder \[[@b23-ce-2018-138]\]. According to the EMA, SCD should be limited to situations where there is a clear clinical indication, after which the patient should be carefully monitored for signs of iron overload and its progression to more serious complications. Even if a patient is not currently presenting with any of the above-mentioned clinical manifestations, a second line of defense may be to use SCD in the following situations: patients with preexisting risk factors for iron overload (e.g., inflammation, conditions requiring bone marrow transplantation, chemotherapy, transfusion therapy), patients in remission from acute myeloid leukemia or acute lymphoblastic leukemia who are receiving maintenance therapy with chemotherapy and/or radiotherapy, patients with acquired hemophilia due to an inhibitor, patients who are planning to undergo a large dose of chemotherapy, and patients with inherited hemochromatosis \[[@b24-ce-2018-138]\]. Indications for SCD ===== Hematologists should identify patients in whom SCD is needed to prevent or treat their disease and then offer them the option of receiving transfusion therapy, considering their clinical situation and clinical benefit--risk profile. From my understanding, the code below would achieve this, but for some reason it only converts the first few bytes of the byte[] byte[] bytes = FileTools.readByte(inputStream); String text = new String(bytes); When I debug it, it shows that byte[] "bytes" only contains 6 bytes. Any help is appreciated A: You should be using: String text = new String(bytes, "UTF-8"); This will convert bytes to UTF-8 text. You can read more about the class String in the documentation. A: You're trying to take a raw byte array and convert it into a string. However, "string" is a sequence of characters, in other words a sequence of bytes that have a particular encoding. A "raw" byte array is a sequence of bytes that has no encoding. If you want a byte array to be interpreted as a string, you should be converting it into a byte[] first: String text = new String(bytes);

A: The short answer to your question is "No". The long answer would be
