with us, please contact the video's host instead. In situ immuno-electron microscopy of infected chick embryo cells. The establishment of cell-cell and cell-extracellular matrix interactions requires the targeting of proteins to subcellular compartments, the proper localization of the proteins to the site of function, and the control of their temporal and spatial dynamics. The extracellular matrix of many tissues is generated by the coordinated activity of cells that secrete laminin, collagen,

---

heparan sulfate proteoglycans, and other matrix molecules. In addition, there are many proteins that are expressed transiently and/or at a restricted site. One way in which a cell is able to control the expression, localization, and turnover of specific matrix proteins is by regulating the localization of their matricryptin (or tyrosine sulfate proteoglycan) precursors. The matricryptin molecules are then modified in a tissue-specific manner and may be deposited as a matrix

---

molecule. Recently, we have developed techniques to monitor the subcellular localization of these matricryptin precursors and have applied these techniques to studies of matricryptin subcellular targeting in living cells in situ. Here, we describe a method for immunoelectron microscopy of primary chick embryo fibroblasts that have been infected with a temperature-sensitive mutant of vesicular stomatitis virus. The main goal of the proposed research is to understand the mechanisms of initiation

---

of myogenesis in the *C. elegans* embryo. Myogenesis is the process by which the somatic mesoderm of the *C. elegans* embryo forms muscle. This is the first step in myogenesis and occurs during embryogenesis. The key to understanding the molecular mechanisms of
